Project 1--CDA 3101 (Spring 2014)

Worth: 100 points (10% of course grade)
Assigned: Friday, Jan 24, 2014
Due: 1:25 pm, Monday, Feb 24, 2014

1. Purpose

This project is intended to help you understand the instructions of a very simple assembly language and how to assemble programs into machine language.

2. Problem

This project has three parts. In the first part, you will write a program to take an assembly-language program and produce the corresponding machine language. In the second part, you will write a behavioral simulator for the resulting machine code. In the third part, you will write a short assembly-language program to multiply two numbers.

3. LC3101 Instruction-Set Architecture

```
bits 24-22: opcode
bits 21-19: reg A
bits 18-16: reg B
bits 15-0:  offsetField (16-bit, range of -
```

---

4. LC3101 Assembly Language and Assembler (40%)

The first part of this project is to write a program to take an assembly-language program and translate it into machine language. You will translate assembly-language names for instructions, such as beq, into their numeric equivalent (e.g. 100), and you will translate symbolic names for addresses into numeric values. The final output will be a series of 32-bit instructions (instruction bits 31-25 are always 0).

The format for a line of assembly code is:

label instruction field0 field1 field2 comments

The leftmost field on a line is the label field. Valid labels contain a maximum of 6 characters and can consist of letters and numbers (but must start with a letter). The label is optional (the white space following the label field is required). Labels make it much easier to write assembly-language programs, since otherwise you would need to modify all address fields each time you added a line to your assembly-language program!

After the optional label is white space which consists of any number of space or tab characters. The writespace is followed by the instruction field, where the instruction can be any of the assembly-language instruction names listed in the above table. After more white space comes a series of fields.
All fields are given as decimal numbers or labels. The number of fields depends on the instruction, and unused fields should be ignored (treat them like comments).

R-type instructions (add, nand) instructions require 3 fields: field0 is regA, field1 is regB, and field2 is destReg.

I-type instructions (lw, sw, beq) require 3 fields: field0 is regA, field1 is regB, and field2 is either a numeric value for offsetField or a symbolic address. Numeric offsetFields can be positive or negative; symbolic addresses are discussed below.

O-type instructions (noop and halt) require no fields.

Symbolic addresses refer to labels. For lw or sw instructions, the assembler should compute offsetField to be equal to the address of the label. This could be used with a zero base register to refer to the label, or could be used with a non-zero base register to index into an array starting at the label. For beq instructions, the assembler should translate the label into the numeric offsetField needed to branch to that label.

After the last used field comes more white space, then any comments. The comment field ends at the end of a line. Comments are vital to creating understandable assembly-language programs, because the instructions themselves are rather cryptic.

In addition to LC3101 instructions, an assembly-language program may contain directions for the assembler. The only assembler directive we will use is .fill (note the leading period). .fill tells the assembler to put a number into the place where the instruction would normally be stored. .fill instructions use

```
neg1  .fill -1
stAddr      .fill start            will contain the address of start (2)
```

And here is the corresponding machine language:

```
(address 0): 8454151 (hex 0x810007)
(address 1): 9043971 (hex 0x8a0003)
(address 2): 655361 (hex 0xa0001)
(address 3): 16842754 (hex 0x1010002)
(address 4): 16842749 (hex 0x100fffd)
(address 5): 29360128 (hex 0x1c00000)
(address 6): 25165824 (hex 0x1800000)
(address 7): 5 (hex 0x5)
(address 8): -1 (hex 0xffffffff)
(address 9): 2 (hex 0x2)
```

Be sure you understand how the above assembly-language program got translated
to machine language.

Since your programs will always start at address 0, your program should only
output the contents, not the addresses.

```
8454151
9043971
655361

16842749
29360128
25165824
5
-1
2
```

4.1. Running Your Assembler

line arguments. The first argument is
the file name where the assembly-language program is stored, and the second
argument is the file name where the output (the machine-code) is written.
For example, with a program name of "assemble", an assembly-language program
in "program.as", the following would generate a machine-code file
"program.mc":

```
    assemble program.as program.mc
```

Note that the format for running the command must use command-line arguments
for the file names (rather than standard input and standard output).
Your

file, one instruction per line. Any deviation from this format (e.g. extra spaces or empty lines) will render your machine-code file ungradable. Any other output that you want the program to generate (e.g. debugging output) can be printed to standard output.

4.2. Error Checking

Your assembler should catch the following errors in the assembly-language program: use of undefined labels, duplicate labels, offsetFields that don't fit in 16 bits, and unrecognized opcodes. Your assembler should exit(1) if it detects an error and exit(0) if it finishes without detecting any errors. Your assembler should NOT catch simulation-time errors, i.e. errors that would occur at the time the assembly-language program executes (e.g. branching to address -1, infinite loops, etc.).

4.3. Test Cases

An integral (and graded) part of writing your assembler will be to write a suite of test cases to validate any LC3101 assembler. This is common practice in the real world--software companies maintain a suite of test cases for their programs and use this suite to check the program's correctness after a change. Writing a comprehensive suite of test cases will deepen your understanding of the project specification and your program, and it will help you a lot as you debug your program.

The test cases for the assembler part of this project will be short assembly-language programs that serve as input to an assembler. You will submit your suite of test cases together with your assembler, and we will grade your test suite according to how thoroughly it exercises an assembler. Each test case may be at most 50 lines long, and your test suite may contain up to 20 test cases. These limits are much larger than needed for full credit (the solution test suite is composed of 5 test cases, each < 10 lines long). See Section 7 for how your test suite will be graded.

Hints: the example assembly-language program above is a good case to include
in your test suite, though you'll need to write more test cases to get full
credit. Remember to create some test cases that test the ability of an assembler to check for the errors in Section 4.2.

4.4. Assembler Hints

Asth the assembler 1 7,.e9 you will write a 1 7s.e9uite of test case0 1 75.e9to vali

[redacted]

to
itself. Given the LC3101 instruction set, it's easiest to modify the algorithm so that you avoid the right shift. Submit a version of the program
that computes (32766 * 10383).

Your multiplication program must be reasonably efficient--it must be at most
50 lines long and execute at most 1000 instructions for any valid numbers (this
is several times longer and slower than the solution). To achieve this, you
must use a loop and shift algorithm to perform the multiplication;
algorithms..9812hms

[redacted]

For the simulator test suite, we will correctly assemble each test case, then use it as input to a set of buggy simulators. A test case exposes a buggy simulator by causing it to generate a different answer from a correct simulator. The test suite is graded based on how many of the buggy
simulators were exposed by at least one test case.

8. Turning in the Project

Submit you files through blackboard.
Each part should be archived in a .tar or .zip file to help with grading.

Here are the files you should submit for each project part:

1) assembler (part 1a)
    a. C/C++ program for your assembler

You may also choose to not use this fragment.

```
/* Assembler code fragment for LC3101 */

#include <stdlib.h>
#include <stdio.h>
#include <string.h>

#define MAXLINELENGTH 1000

int readAndParse(FILE *, char *, char *, char *, char *, char *);
int isNumber(char *);

int
main(int argc, char *argv[])
{
    char *inFileString, *outFileString;
    FILE *inFilePtr, *outFilePtr;
    char label[MAXLINELENGTH], opcode[MAXLINELENGTH],
arg0[MAXLINELENGTH],
            arg1[MAXLINELENGTH], arg2[MAXLINELENGTH];

    if (argc != 3) {
        printf("error: usage: %s <assembly-code-file> <machine-code-
file>\n",
            argv[0]);
        exit(1);
    }

    inFileString = argv[1];
    outFileString = argv[
```

```
    /* after doing a readAndParse, you may want to do the following to
test the
        opcode */
    if (!strcmp(opcode, "add")) {
        /* do whatever you need to do for opcode "add" */
    }

    return(0);
}

/*
 * Read and parse a line of the assembly-language file.  Fields are
returned
 * in label, opcode, arg0, arg1, arg2 (these strings must have memory
already
 * allocated to them).
 *
 * Return values:
 *     0 if reached end of file
 *     1 if all went well
 *
 * exit(1) if line is too long.
 */
int
readAndParse(FILE *inFilePtr, char *label, char *opcode, char *arg0,
    char *arg1, char *arg2)
{
    char line[MAXLINELENGTH];
    char *ptr = line;

    /* delete prior values */
    label[0] = opcode[0] = arg0[0] = arg1[0] = arg2[0] = '\0';

    /* read the line from the assembly-language file */
    if (fgets(line, MAXLINELENGTH, inFilePtr) == NULL) {
      /* reached end of file */
        return(0);
    }

    /* check for line too long (by looking for a \n) */
    if (strchr(line, '\n') == NULL) {
        /* line too long */
      printf("error: line too long\n");
      exit(1);
    }

    /* is there a label? */
    ptr = line;
    if (sscanf(ptr, "%[^\t\n ]", label)) {
      /* successfully read label; advance pointer over the label */
        ptr += strlen(label);
    }

    /*
```

```
     * Parse the rest of the line.  Would be nice to have real regular
     * expressions, but scanf will suffice.
     */
    sscanf(ptr, "%*[\t\n ]%[^\t\n ]%*[\t\n ]%[^\t\n ]%*[\t\n ]%[^\t\n
]%*[\t\n ]%[^\t\n ]",
        opcode, arg0, arg1, arg2);
    return(1);
}

int
isNumber(char *string)
{
    /* return 1 if string is a number */
    int i;
    return( (sscanf(string, "%d", &i)) == 1);
}
```

10. Code Fragment for Simulator

Here is some C code that may help you write the simulator. Again, you should
take this merely as a hint. You may have to re-code this to make it do exactly
what you want, but this should help you get started. Remember not to change stateStruct or printState.

```
/* instruction-level simulator for LC3101 */

#include <stdio.h>
#include <string.h>

#define NUMMEMORY 65536 /* maximum number of words in memory */
#define NUMREGS 8 /* number of machine registers */
#define MAXLINELENGTH 1000

typedef struct stateStruct {
    int pc;
    int mem[NUMMEMORY];
    int reg[NUMREGS];
    int numMemory;
} stateType;

void printState(stateType *);

int
main(int argc, char *argv[])
{
    char line[MAXLINELENGTH];
    stateType state;
    FILE *filePtr;

    if (argc != 2) {
```

```
      printf("error: usage: %s <machine-code file>\n", argv[0]);
      exit(1);
    }

    filePtr = fopen(argv[1], "r");
    if (filePtr == NULL) {
      printf("error: can't open file %s", argv[1]);
      perror("fopen");
      exit(1);
    }

    /* read in the entire machine-code file into memory */
    for (state.numMemory = 0; fgets(line, MAXLINELENGTH, filePtr) !=
NULL;
      state.numMemory++) {
      if (sscanf(line, "%d", state.mem+state.numMemory) != 1) {
          printf("error in reading address %d\n", state.numMemory);
          exit(1);
      }
      printf("memory[%d]=%d\n", state.numMemory,
state.mem[state.numMemory]);
    }

    return(0);
}

void
printState(stateType *statePtr)
{
    int i;
    printf("\n@@@\nstate:\n");
    printf("\tpc %d\n", statePtr->pc);
    printf("\tmemory:\n");
      for (i=0; i<statePtr->numMemory; i++) {
          printf("\t\tmem[ %d ] %d\n", i, statePtr->mem[i]);
      }
    printf("\tregisters:\n");
      for (i=0; i<NUMREGS; i++) {
          printf("\t\treg[ %d ] %d\n", i, statePtr->reg[i]);
      }
    printf("end state\n");
}
```

11. Programming Tips

Here are a few programming tips for writing C/C++ programs to manipulate bits:

1) To indicate a hexadecimal constant in, precede the number by 0x. For example, 27 decimal is 0x1b in hexadecimal.

2) The value of the expression (a >> b) is the number "a" shifted right by "b"

bits. Neither a nor b are changed. E.g. (25 >> 2) is 6. Note that 25 is 11001 in
binary, and 6 is 110 in binary.

3) The value of the expression (a << b) is the number "a" shifted left by "b"
bits. Neither a nor b are changed. E.g. (25 << 2) is 100. Note that 25 is 11001
in binary, and 100 is 1100100 in binary.

4) To find the value of the expression (a & b), perform a logical AND on each
bit of a and b (i.e. bit 31 of a ANDED with bit 31 of b, bit 30 of a ANDED with
bit 30 of b, etc.). E.g. (25 & 11) is 9, since:

```
    11001 (binary)
  & 01011 (binary)
---------------------
 =  01001 (binary), which is 9 decimal.
```

5) To find the value of the expression (a | b), perform a logical OR on each bit
of a and b (i.e. bit 31 of a ORED with bit 31 of b, bit 30 of a ORED with bit 30
of b, etc.). E.g. (25 | 11) is 27, since:

```
    11001 (binary)
  & 01011 (binary)
---------------------
 =  11011 (binary), which is 27 decimal.
```

6) ~a is the bit-wise complement of a (a is not changed).

Use these operations to create and manipulate machine-code. E.g. to look at bit
3 of the variable a, you might do: (a>>3) & 0x1. To look at bits (bits 15-12) of
a 16-bit word, you could do: (a>>12) & 0xF. To put a 6 into bits 5-3 and a 3
into bits 2-1, you could do: (6<<3) | (3<<1). If you're not sure what an
operation is doing, print some intermediate results to help you debug.

---
