

Project 1--CDA 3101 (Spring 2014)

Worth: 100 points (10% of course grade)

Assigned: Friday, Jan 24, 2014

Due: 1:25 pm, Monday, Feb 24, 2014

1. Purpose

This project is intended to help you understand the instructions of a very simple assembly language and how to assemble programs into machine language.

2. Problem

This project has three parts. In the first part, you will write a program to take an assembly-language program and produce the corresponding machine language. In the second part, you will write a behavioral simulator for the resulting machine code. In the third part, you will write a short assembly-language program to multiply two numbers.

3. LC3101 Instruction-Set Architecture

For this project, you will be developing a simulator and assembler for the LC3101 (Little Computer, used in CDA 3101). The LC3101 is very simple, but

```
negl .fill -1
stAddr .fill start          will contain the address of start (2)
```

And here is the corresponding machine language:

```
(address 0): 8454151 (hex 0x810007)
(address 1): 9043971 (hex 0x8a0003)
(address 2): 655361 (hex 0xa0001)
(address 3): 16842754 (hex 0x1010002)
(address 4): 16842749 (hex 0x100fffd)
(address 5): 29360128 (hex 0x1c00000)
(address 6): 25165824 (hex 0x1800000)
(address 7): 5 (hex 0x5)
(address 8): -1 (hex 0xffffffff)
(address 9): 2 (hex 0x2)
```

Be sure you understand how the above assembly-language program got translated to machine language.

Since your programs will always start at address 0, your program should only output the contents, not the addresses.

```
8454151
9043971
655361
16842754
16842749
29360128
```

file, one instruction per line. Any deviation from this format (e.g. extra spaces or empty lines) will render your machine-code file ungradable. Any other output that you want the program to generate (e.g. debugging output) can be printed to standard output.

4.2. Error Checking

Your assembler should catch the following errors in the assembly-language program: use of undefined labels, duplicate labels, offsetFields that don't fit in 16 bits, and unrecognized opcodes. Your assembler should exit(1) if it detects an error and exit(0) if it finishes without detecting any errors. Your assembler should NOT catch simulation-time errors, i.e. errors that would occur at the time the assembly-language program executes (e.g. branching to address -1, infinite loops, etc.).

4.3. Test Cases

An integral (and graded) part of writing your assembler will be to write a suite of test cases to validate any LC3101 assembler. This is common practice in the real world--software companies maintain a suite of test cases for their programs and use this suite to check the program's correctness after a change. Writing a comprehensive suite of test cases will deepen your understanding of the project specification and your program, and it will help you a lot as you debug your program.

The test cases for the assembler part of this project will be short assembly language programs that serve as input to an assembler. You will submit your suite of test cases together with your assembler, and we will grade your test suite according to how thoroughly it exercises an assembler. Each test case may be at most 50 lines long, and your test suite may contain up to 20 test cases. These limits are much larger than needed for full credit (the solution test suite is composed of 5 test cases, each < 10 lines long). See Section 7 for how your test suite will be graded.

As with the assembler, you will write a suite of test cases to validate the LC3101 simulator.

The test cases for the simulator part of this project will be short assembly-language programs that, after being assembled into machine code, serve as input to a simulator. You will submit your suite of test cases together with your simulator, and we will grade your test suite according to how thoroughly it exercises an LC3101 simulator. Each test case may execute at most 200 instructions on a correct simulator, and your test suite may contain up to 20 test cases. These limits are much larger than needed for full credit (the solution test suite is composed of a couple test cases, each executing less than 40 instructions). See Section 7 for how your test suite will be graded.

5.2. Simulator Hints

Be careful how you handle `offsetField` for `lw`, `sw`, and `beq`. Remember that it's a 2's complement 16-bit number, so you need to convert a negative `offsetField` to a negative 32-bit integer on the Sun workstations (by sign extending it). To do this, use the following function.

```
int
convertNum(int num)
{
    /* convert a 16-bit number into a 32-bit Sun integer */
    if (num & (1<<15) ) {
        num -= (1<<16);
    }
    return(num);
}
```

An example run of the simulator (not for the specified task of multiplication) is included at the end of this posting.

6. Assembly-Language Multiplication (20%)

The third part of this assignment is to write an assembly-language program to multiply two numbers. Input the numbers by reading memory locations called

program halts. You may assume that the two input numbers are at most 15 bits and are positive; this ensures that the (positive) result fits in an LC3101 word. See the algorithm on page 252 of the textbook for how to multiply. Remember that shifting left by one bit is the same as adding the number to itself. Given the LC3101 instruction set, it's easiest to modify the algorithm so that you avoid the right shift. Submit a version of the program that computes $(32766 * 10383)$.

Your multiplication program must be reasonably efficient--it must be at most 50 lines long and execute at most 1000 instructions for any valid numbers (this is several times longer and slower than the solution). To achieve this, you must use a loop and shift algorithm to perform the multiplication; algorithms such as successive addition (e.g. multiplying $5 * 6$ by adding 5 six times) will take too long.

7. Grading and Formatting

We will grade primarily on functionality, including error handling, correctly assembling and simulating all instructions, input and output format, method of executing your program, correctly multiplying, and comprehensiveness of the test suites.

The best way to debug your program is to generate your own test cases, figure out the correct answers, and compare your program's output to the correct answers. This is also one of the best ways to learn the concepts in the project.

The student suite of test cases for the assembler and simulator parts of this project will be graded according to how thoroughly they test an LC3101 assembler or simulator. We will judge thoroughness of the test suite by how well it exposes potentially bugs in an assembler or simulator.

For the assembler test suite, we will use each test case as input to a set of buggy assemblers. A test case exposes a buggy assembler by causing it to generate a different answer from a correct assembler. The test suite is graded based on how many of the buggy assemblers were exposed by at least one test case. This is known as "mutation testing" in the research literature on automated testing.

For the simulator test suite, we will correctly assemble each test case, then use it as input to a set of buggy simulators. A test case exposes a buggy simulator by causing it to generate a different answer from a correct simulator. The test suite is graded based on how many of the buggy simulators were exposed by at least one test case.

8. Turning in the Project

Submit your files through blackboard.
Each part should be archived in a .tar or .zip file to help with grading.

Here are the files you should submit for each project part:

- 1) assembler (part 1a)
 - a. C/C++ program for your assembler
 - b. suite of test cases (each test case is an assembly-language program in a separate file)
- 2) simulator (part 1s)
 - a. C/C++ program for your simulator
 - b. suite of test cases (each test case is an assembly-language program in a separate file)
- 3) multiplication (part 1m)
 - a. assembly program for multiplication

Your assembler and simulator must each be in a single C or C++ file. We will compile your program on linprog using "gcc program.c -lm" (or g++), so your program should not require additional compiler flags or libraries.

The official time of submission for your project will be the time the last file is sent. If you send in anything after the due date, your project will be considered late (and will use up your late days or will receive a zero).

9. Code Fragment for Assembler

The focus of this class is machine organization, not C programming skills. To "build" your computer, however, you will be doing a lot of C programming. To help you, here is a fragment of the C program for the assembler. This shows how to specify command-line arguments to the program (via argc and argv), how to parse the assembly-language file, etc.. This fragment is provided strictly to help you, though it may take a bit for you to understand and use the file.

You may also choose to not use this fragment.

```
/* Assembler code fragment for LC3101 */
```

```
#include <stdlib.h>
```

```
#include <stdio.h>
```

```
#include <string.h>
```

```
#define MAXLINELENGTH 1000
```

```
int readAndParse(FILE *, char *, char *, char *, char *, char *);
```

```
int isNumber(char *);
```

```
int
```

```
main(int argc, char *argv[])
```

```
{
```

```
    char *inFileString, *outFileString;
```

```
    FILE *inFilePtr, *outFilePtr;
```

```
    char label[MAXLINELENGTH], opcode[MAXLINELENGTH],
```

```
    arg0[MAXLINELENGTH],
```

```
        arg1[MAXLINELENGTH], arg2[MAXLINELENGTH];
```

```
    if (argc != 3) {
```

```
        printf("error: us] TJ8(or:  )7%rsz~{I6Cs^6Cs\}5Cs^7Cs|I6YCs^6'T756Cs^6666
```

```

    /* after doing a readAndParse, you may want to do the following to
test the
        opcode */
    if (!strcmp(opcode, "add")) {
        /* do whatever you need to do for opcode "add" */
    }

    return(0);
}

/*
 * Read and parse a line of the assembly-language file. Fields are
returned
 * in label, opcode, arg0, arg1, arg2 (these strings must have memory
already
 * allocated to them).
 *
 * Return values:
 *     0 if reached end of file
 *     1 if all went well
 *
 * exit(1) if line is too long.
 */
int
readAndParse(FILE *inFilePtr, char *label, char *opcode, char *arg0,
             char *arg1, char *arg2)
{
    char line[MAXLINELENGTH];
    char *ptr = line;

    /* delete prior values */
    label[0] = opcode[0] = arg0[0] = arg1[0] = arg2[0] = '\0';

    /* read the line from the assembly-language file */
    if (fgets(line, MAXLINELENGTH, inFilePtr) == NULL) {
        /* reached end of file */
        return(0);
    }

    /* check for line too long (by looking for a \n) */
    if (strchr(line, '\n') == NULL) {
        /* line too long */
        printf("error: line too long\n");
        exit(1);
    }

    /* is there a label? */
    ptr = line;
    if (sscanf(ptr, "%[^\\t\\n ]", label)) {
        /* successfully read label; advance pointer over the label */
        ptr += strlen(label);
    }

    /*

```

```

        * Parse the rest of the line.  Would be nice to have real regular
        * expressions, but scanf will suffice.
        */
        sscanf(ptr, "%*[\t\n ]%[^\\t\\n ]%*[\t\n ]%[^\\t\\n ]%*[\t\n ]%[^\\t\\n
]%^*[\t\n ]%[^\\t\\n ]",
               opcode, arg0, arg1, arg2);
        return(1);
    }

int
isNumber(char *string)
{
    /* return 1 if string is a number */
    int i;
    return( (sscanf(string, "%d", &i)) == 1);
}

```

10. Code Fragment for Simulator

Here is some C code that may help you write the simulator. Again, you should take this merely as a hint. You may have to re-code this to make it do exactly what you want, but this should help you get started. Remember not to change stateStruct or printState.

```

/* instruction-level simulator for LC3101 */

#include <stdio.h>
#include <string.h>

#define NUMMEMORY 65536 /* maximum number of words in memory */
#define NUMREGS 8 /* number of machine registers */
#define MAXLINELENGTH 1000

typedef struct stateStruct {
    int pc;
    int mem[NUMMEMORY];
    int reg[NUMREGS];
    int numMemory;
} stateType;

void printState(stateType *);

int
main(int argc, char *argv[])
{
    char line[MAXLINELENGTH];
    stateType state;
    FILE *filePtr;

    if (argc != 2) {

```

bits. Neither a nor b are changed. E.g. (25 >> 2) is 6. Note that 25 is 11001 in binary, and 6 is 110 in binary.

3) The value of the expression (a << b) is the number "a" shifted left by "b" bits. Neither a nor b are changed. E.g. (25 << 2) is 100. Note that 25 is 11001 in binary, and 100 is 1100100 in binary.

4) To find the value of the expression (a & b), perform a logical AND on each bit of a and b (i.e. bit 31 of a AND'ed with bit 31 of b, bit 30 of a AND'ed with bit 30 of b, etc.). E.g. (25 & 11) is 9, since:

```
      11001 (binary)
      & 01011 (binary)
      -----
      = 01001 (binary), which is 9 decimal.
```

5) To find the value of the expression (a | b), perform a logical OR on each bit of a and b (i.e. bit 31 of a OR'ed with bit 31 of b, bit 30 of a OR'ed with bit 30 of b, etc.). E.g. (25 | 11) is 27, since:

```
      11001 (binary)
      & 01011 (binary)
      -----
      = 11011 (binary), which is 27 decimal.
```

6) ~a is the bit-wise complement of a (a is not changed).

Use these operations to create and manipulate machine-code. E.g. to look at bit 3 of the variable a, you might do: (a>>3) & 0x1. To look at bits (bits 15-12) of a 16-bit word, you could do: (a>>12) & 0xF. To put a 6 into bits 5-3 and a 3 into bits 2-1, you could do: (6<<3) | (3<<1). If you're not sure what an operation is doing, print some intermediate results to help you debug.

12. Example Run of Simulator

```
memory[0]=8454151
memory[1]=9043971
memory[2]=655361
memory[3]=16842754
memory[4]=16842749
memory[5]=29360128
memory[6]=25165824
```

```
memory[7]=5
memory[8]=-1
memory[9]=2
```
