

Project 1--CDA 3101 (Spring 2014)

Worth: 100 points (10% of course grade)

Assigned: Friday, Jan 24, 2014

Due: 1:25 pm, Monday, Feb 24, 2014

1. Purpose

This project is intended to help you understand the instructions of a very simple assembly language and how to assemble programs into machine language.

2. Problem

This project has three parts. In the first part, you will write a program to take an assembly-language program and produce the corresponding machine language. In the second part, you will write a behavioral simulator for the resulting machine code. In the third part, you will write a short assembly-language program to multiply two numbers.

3. LC3101 Instruction-Set Architecture

For this project, you will be developing a simulator and assembler for the LC3101 (Little Computer, used in CDA 3101). The LC3101 is very simple, but it is general enough to solve complex problems. For this project, you will only need to know the instruction set and instruction format of the LC3101.

The LC3101 is an 8-register, 32-bit computer. All addresses are word-addresses (unlike MIPS which is byte-addressed). The LC3101 has 65536 words of memory. By assembly-language convention, register 0 will always contain 0 (i.e. the machine will not enforce this, but no assembly-language program should ever change register 0 from its initial value of 0).

There are 3 instruction formats (bit 0 is the least-significant bit). Bits 31-25 are unused for all instructions, and should always be 0.

R-type instructions (add, nand):

- bits 24-22: opcode
- bits 21-19: reg A
- bits 18-16: reg B
- bits 15-3: unused (should all be 0)
- bits 2-0: destReg

I-type instructions (lw, sw, beq):

bits 24-22: opcode
 bits 21-19: reg A
 bits 18-16: reg B
 bits 15-0: offsetField (16-bit, range of -32768 to 32767)

O-type instructions (halt, noop):
 bits 24-22: opcode
 bits 21-0: unused (should all be 0)

Table 1: Description of Machine Instructions

Assembly language name for instruction	Opcode in binary (bits 24, 23, 22)	Action
add (R-type format)	000	add contents of regA with contents of regB, store results in destReg.
nand (R-type format)	001	nand contents of regA with contents of regB, store results in destReg.
lw (I-type format)	010	load regB from memory. Memory address is formed by adding offsetField with the contents of regA.
sw (I-type format)	011	store regB into memory. Memory address is formed by adding offsetField with the contents of regA.
beq (I-type format)	100	if the contents of regA and regB are the same, then branch to the address PC+1+offsetField, where PC is the address of the beq instruction.
cmov (R-type)	101	copy the value regA into destReg if the contents of regB != 0
halt (O-type format)	110	increment the PC (as with all instructions), then halt the machine (let the simulator notice that the machine halted).
noop (O-type format)	111	do nothing except increment PC.

4. LC3101 Assembly Language and Assembler (40%)

The

Symbolic addresses refer to labels. For lw or sw instructions, the assembler should compute offsetField to be equal to the address of the label. This could be used with a zero base register to refer to the label, or could be used with a non - zero base register to index into an array starting at the label.

```
negl .fill -1
stAddr .fill start          will contain the address of start (2)
```

And here is the corresponding machine language:

```
(address 0): 8454151 (hex 0x810007)
(address 1): 9043971 (hex 0x8a0003)
```

file, one instruction per line. Any deviation from this format (e.g.
extra

Hints: the example assembly-language program above is a good case to include in your test suite, though you'll need to write more test cases to get full credit. Remember to create some test cases that test the ability of an assembler to check for the errors in Section 4.2.

4.4. Assembler Hints

Since `offsetField` is a 2's

program halts. You may assume that the two input numbers are at most 15 bits and are positive; this ensures that the (positive) result fits in an LC3101 word. See the algorithm on page 252 of the textbook for how to multiply. Remember that shifting left by one bit is the same as adding the number to itself. Given the LC3101 instruction set, it's easiest to modify the algorithm so that you avoid the right shift. Submit a version of the program that computes $(32766 * 10383)$.

Your multiplication program must be reasonably efficient--it must be at most 50 lines long and execute at most 1000 instructions for any valid numbers (this is several times longer and slower than the solution). To achieve this, you must use a loop and shift algorithm to perform the multiplication; algorithms such as successive addition (e.g. multiplying $5 * 6$ by adding 5 six times) will take too long.

7. Grading and Formatting

We will grade primarily on functionality, including error handling, correctly assembling and simulating all instructions, input and output format, method of executing your program, correctly multiplying, and comprehensiveness of the test suites.

The best way to debug your program is to generate your own test cases, figure out the correct answers, and compare your program's output to the correct answers. This is also one of the best ways to learn the concepts in the project.

The student suite of test cases for the assembler and simulator parts of this project will be graded according to how thoroughly they test an LC3101 assembler or simulator. We will judge thoroughness of the test suite by how well it exposes potentially bugs in an assembler or simulator.

For the assembler test suite, we will use each test case as input to a set of buggy assemblers. A test case exposes a buggy assembler by causing it to generate a different answer from a correct assembler. The test suite is graded based on how many of the buggy assemblers were exposed by at least one test case. This is known as "mutation testing" in the research literature on automated testing.

For the simulator test suite, we will correctly assemble each test case, then use it as input to a set of buggy simulators. A test case exposes a buggy simulator by causing it to generate a different answer from a correct simulator. The test suite is graded based on how many of the buggy simulators were exposed by at least one test case.

8. Turning in the Project

Submit your files through blackboard.
Each part should be archived in a .tar or .zip file to help with grading.

Here are the files you should submit for each project part:

- 1) assembler (part 1a)
 - a. C/C++ program for your assembler

You may also choose to not use this fragment.

```
/* Assembler code defrr
```

```

    /* after doing a readAndParse, you may want to do the following to
test the
        opcode */
    if (!strcmp(opcode, "add")) {
        /* do whatever you need to do for opcode "add" */
    }

    return(0);
}

/*
 * Read and parse a line of the assembly-language file. Fields are
returned
 * in label, opcode, arg0, arg1, arg2 (these strings must have memory
already
 * allocated to them).
 *
 * Return values:
 *     0 if reached end of file
 *     1 if all went well
 *
 * exit(1) if line is too long.
 */
int
readAndParse(FILE *inFilePtr, char *label, char *opcode, char *arg0,
             char *arg1, char *arg2)
{
    char line[MAXLINELENGTH];
    char *ptr = line;

    /* delete prior values */
    label[0] = opcode[0] = arg0[0] = arg1[0] = arg2[0] = '\0';

    /* read the line from the assembly-language file */
    if (fgets(line, MAXLINELENGTH, inFilePtr) == NULL) {
        /* reached end of file */
        return(0);
    }

    /* check for line too long (by looking for a \n) */
    if (strchr(line, '\n') == NULL) {
        /* line too long */
        printf("error: line too long\n");
        exit(1);
    }

    /* is there a label? */
    ptr = line;
    if (sscanf(ptr, "%[^\\t\\n ]", label)) {
        /* successfully read label; advance pointer over the label */
        ptr += strlen(label);
    }

    /*

```

```

        * Parse the rest of the line.  Would be nice to have real regular
        * expressions, but scanf will suffice.
        */
        sscanf(ptr, "%*[\t\n ]%[^\\t\\n ]%*[\t\n ]%[^\\t\\n ]%*[\t\n ]%[^\\t\\n
]%^*[\t\n ]%[^\\t\\n ]",
               opcode, arg0, arg1, arg2);
        return(1);
    }

int
isNumber(char *string)
{
    /* return 1 if string is a number */
    int i;
    return( (sscanf(string, "%d", &i)) == 1);
}

```

10. Code Fragment for Simulator

Here is some C code that may help you write the simulator. Again, you should take this merely as a hint. You may have to re-code this to make it do exactly what you want, but this should help you get started. Remember not to change stateStruct or printState.

```

/* instruction-level simulator for LC3101 */

#include <stdio.h>
#include <string.h>

#define NUMMEMORY 65536 /* maximum number of words in memory */
#define NUMREGS 8 /* number of machine registers */
#define MAXLINELENGTH 1000

typedef struct stateStruct {
    int pc;
    int mem[NUMMEMORY];
    int reg[NUMREGS];
    int numMemory;
} stateType;

void printState(stateType *);

int
main(int argc, char *argv[])
{
    char line[MAXLINELENGTH];
    stateType state;
    FILE *filePtr;

    if (argc != 2) {

```

bits. Neither a nor b are changed. E.g. $(25 \gg 2)$ is 6. Note that 25 is 11001 in binary, and 6 is 110 in binary.

3) The value of the expression $(a \ll b)$ is the number "a" shifted left by "b" bits. Neither a nor b are changed. E.g. $(25 \ll 2)$ is 100. Note that 25 is 11001 in binary, and 100 is 1100100 in binary.

4) To find the value of the expression $(a \& b)$, perform a logical AND on each bit of a and b (i.e. bit 31 of a ANDED with bit 31 of b, bit 30 of a ANDED with bit 30 of b, etc.). E.g. $(25 \& 11)$ is 9, since:

```
      11001 (binary)
      & 01011 (binary)
      -----
      = 01001 (binary), which is 9 decimal.
```

5) To find the value of the expression $(a | b)$, perform a logical OR on each bit of a and b (i.e. bit 31 of a ORED with bit 31 of b, bit 30 of a ORED with bit 30 of b, etc.). E.g. $(25 | 11)$ is 27, since:

```
      11001 (binary)
      & 01011 (binary)
      -----
      = 11011 (binary), which is 27 decimal.
```

6) $\sim a$ is the bit-wise complement of a (a is not changed).

Use these operations to create and manipulate machine-code. E.g. to look at bit 3 of the variable a, you might do: $(a \gg 3) \& 0x1$. To look at bits (bits 15-12) of a 16-bit word, you could do: $(a \gg 12) \& 0xF$. To put a 6 into bits 5-3 and a 3 into bits 2-1, you could do: $(6 \ll 3) | (3 \ll 1)$. If you're not sure what an operation is doing, print some intermediate results to help you debug.

12. Example Run of Simulator

```
memory[0]=8454151
memory[1]=9043971
memory[2]=655361
memory[3]=16842754
memory[4]=16842749
memory[5]=29360128
memory[6]=25165824
```

```
memory[7]=5
memory[8]=-1
memory[9]=2
```
