

Project 1--CDA 3101 (Spring 2014)

Worth: 100 points (10% of course grade)

Assigned: Friday, Jan 24, 2014

Due: 1:25 pm, Monday, Feb 24, 2014

1. Purpose

This project is intended to help you understand the instructions of a very simple assembly language and how to assemble programs into machine language.

2. Problem

This project has three parts. In the first part, you will write a program to take an assembly-language program and produce the corresponding machine language. In the second part, you will write a behavioral simulator for the resulting machine code. In the third part, you will write a short assembly-language program to multiply two numbers.

3. LC3101 Instruction-Set Architecture

For this project, you will be developing a simulator and assembler for the LC3101 (Little Computer, used in CDA 3101). The LC3101 is very simple, but it is general enough to solve complex problems. For this project, you will only need to know the instruction set and instruction format of the LC3101.

The LC3101 is an 8-register, 32-bit computer. All addresses are word-addresses (unlike MIPS which is byte-addressed). The LC3101 has 65536 words of memory. By assembly-language convention, register 0 will always contain 0 (i.e. the machine will not enforce this, but no assembly-language program should ever change register 0 from its initial value of 0).

There are 3 instruction formats (bit 0 is the least-significant bit). Bits 31-25 are unused for all instructions, and should always be 0.

R-type instructions (add, nand):

- bits 24-22: opcode
- bits 21-19: reg A
- bits 18-16: reg B
- bits 15-3: unused (should all be 0)
- bits 2-0: destReg

I-type instructions (lw, sw, beq):

bits 24-22: opcode
bits 21-19: reg A
bits 18-16: reg B
bits 15-

4. LC3101 Assembly Language and Assembler (40%)

The first part of this project is to write a program to take an assembly-language program and translate it into machine language. You will translate assembly-language names for instructions, such as beq, into their numeric equivalent (e.g. 100), and you will translate symbolic names for addresses into numeric values. The final output will be a series of 32-bit instructions (instruction bits 31-25 are always 0).

The format for a line of assembly code is:

label instruction field0 field1 field2 comments

-

Symbolic addresses refer to labels. For lw or sw instructions, the assembler should compute offsetField to be equal to the address of the label. This could be used with a zero base register to refer to the label, or could be used with a non-zero base register to index into an array starting at the label. For beq instructions, the assembler should translate the label into the numeric offsetField needed to branch to that label.

After the last used field comes more white space, then any comments. The comment field ends at the end of a line. Comments are vital to creating understandable assembly-language programs, because the instructions themselves are rather cryptic.

In addition to LC3101 instructions, an assembly-language program may contain directions for the assembler. The only assembler directive we will use is .fill (note the leading period). .fill tells the assembler to put a number into the place where the instruction would normally be stored. .fill instructions use one field, which can be either a numeric value or a symbolic address. For example, ".fill 32" puts the value 32 where the instruction would normally be stored. .fill with a symbolic address will store the address of the label. In the example below, ".fill start" will store the value 2, because the label "start" is at address 2.

The assembler should make two passes over the assembly-language program. In the first pass, it will calculate the address for every symbolic label. Assume that the first instruction is at address 0. In the second pass, it will generate a machine-language instruction (in decimal) for each line of assembly language. For example, here is an assembly-language program (that counts down from 5, stopping when it hits 0).

```
        lw      0      1      five  load reg1 with 5 (uses symbolic address)
        lw      1      2      3     load reg2 with -1 (uses numeric address)
start add
```

```
negl .fill -1
stAddr .fill start          will contain the address of start (2)
```

And here is the corresponding machine language:

```
(address 0): 8454151 (hex 0x810007)
(address 1): 9043971 (hex 0x8a0003)
(address 2): 655361 (hex 0xa0001)
(address 3): 16842754 (hex 0x1010002)
(address 4): 16842749 (hex 0x100fffd)
(address 5): 29360128 (hex 0x1c00000)
(address 6): 25165824 (hex 0x1800000)
(address 7): 5 (hex 0x5)
(address 8): -1 (hex 0xffffffff)
(address 9): 2 (hex 0x2)
```

Be sure you understand how the above assembly-language program got translated to machine language.

Since your programs will always start at address 0, your program should only output the contents, not the addresses.

8454151

```

candle.ofRem2B0E89mT0Creahels5me024est)ZaB0S thA6 test7the)Ahes17h0dC an06 dorBT0 0eg0
assemblerRem187E0ckBf0r0(the)7xf0rstAnise0t0son)400.d) Tm cc0 1 75jr t STmrion i1 0(ov)7

```

Since `offsetField` is a 2's complement number, it can only store numbers ranging from -32768 to 32767. For symbolic addresses, your assembler will compute `offsetField` so that the instruction refers to the correct label.

60 TJ75H4M6) 9/puXZ/MeID 95BTB87C9B6C B32768 t3(325=5 s1C87C BT 0r.ds

As with the assembler, you will write a suite of test cases to validate the LC3101 simulator.

The test cases for the simulator part of this project will be short assembly-language programs that, after being assembled into machine code, serve as input to a simulator. You will submit your suite of test cases together with your s

For the simulator test suite, we will correctly assemble each test case, then use it as input to a set of buggy simulators. A test case exposes a buggy simulator by causing it to generate a different answer from a correct simulator. The test suite is graded based on how many of the buggy simulators were exposed by at least one test case.

8. Turning in the Project

Submit your files through blackboard.
Each part should be archived in a .tar or .zip file to help with grading.

Here are the files you should submit for each project part:

- 1) assembler (part 1a)
 - a. C/C++ program for your assembler
 - b. suite of test cases (each test case is an assembly-language program in a separate file)
- 2) simulator (part 1s)
 - a. C/C++ program for your simulator
 - b. suite of test cases (each test case is an assembly-language program in a separate file)
- 3) multiplication (part 1m)
 - a. assembly program for multiplication

Your assembler and simulator must each be in a single C or C++ file. We will compile your program on linprog using "gcc program.c -lm" (or g++), so your program should not require additional compiler flags or libraries.

The official time of submission for your project will be the time the last file is sent. If you send in anything after the due date, your project will be considered late (and will use up your late days or will receive a zero).

9. Code Fragment for Assembler

The focus of this class is machine organization, not C programming skills. To "build" your computer, however, you will be doing a lot of C programming. To help you, here is a fragment of the C program for the assembler. This shows how to specify command-line arguments to the program (via argc and argv), how to parse the assembly-language file, etc.. This fragment is provided strictly to help you, though it may take a bit for you to understand and use the file.

You may also choose to not use this fragment.

```
/* Assembler code fragment for LC3101 */

#include <stdlib.h>
#include <stdio.h>
#include <string.h>

#define MAXLINELENGTH 1000

int readAndParse(FILE *, char *, char *, char *, char *, char *);
int isNumber(char *);

int
main(int argc, char *argv[])
{
    char *inFileString, *outFileString;
    FILE *inFilePtr, *outFilePtr;
    char label[MAXLINELENGTH], opcode[MAXLINELENGTH],
    arg0[MAXLINELENGTH],
        arg1[MAXLINELENGTH], arg2[MAXLINELENGTH];

    if (argc != 3) {
        printf("error: usage: %s <assembly-code-file> <machine-code-
file>\n",
            argv[0]);
        exit(1);
    }

    inFileString = argv[1];
    outFileString = argv[2];

    inFilePtr = fopen(inFileString, "r");
    if (inFilePtr == NULL) {
        printf("error in opening %s\n", inFileString);
        exit(1);
    }
    outFilePtr = fopen(outFileString, "w");
    if (outFilePtr == NULL) {
        printf("error in opening %s\n", outFileString);
        exit(1);
    }
}
```

```

    /* after doing a readAndParse, you may want to do the following to
test the
    opcode */
    if (!strcmp(opcode, "add")) {
        /* do whatever you need to do for opcode "add" */
    }

    return(0);
}

/*
 * Read and parse a line of the assembly-language file. Fields are
returned
 * in label, opcode, arg0, arg1, arg2 (these strings must have memory
already
 * allocated to them).
 *
 * Return values:
 *     0 if reached end of file
 *     1 if all went well
 *
 * exit(1) if line is too long.
 */
int
readAndParse(FILE *inFilePtr, char *label, char *opcode, char *arg0,
             char *arg1, char *arg2)
{
    char line[MAXLINELENGTH];
    char *ptr = line;

    /* delete prior values */
    label[0] = opcode[0] = arg0[0] = arg1[0] = arg2[0] = '\0';

    /* read the line from the assembly-language file */
    if (fgets(line, MAXLINELENGTH, inFilePtr) == NULL) {
        /* reached end of file */
        return(0);
    }

    /* check for line too long (by looking for a \n) */
    if (strchr(line, '\n') == NULL) {
        /* line too long */
        printf("error: line too long\n");
        exit(1);
    }

    /* is there a label? */
    ptr = line;
    if (sscanf(ptr, "%[^\\t\\n ]", label)) {
        /* successfully read label; advance pointer over the label */
        ptr += strlen(label);
    }

    /*

```

```

        * Parse the rest of the line.  Would be nice to have real regular
        * expressions, but scanf will suffice.
        */
        sscanf(ptr, "%*[\t\n ]%[^\\t\\n ]%*[\t\n ]%[^\\t\\n ]%*[\t\n ]%[^\\t\\n
]%^*[\t\n ]%[^\\t\\n ]",
               opcode, arg0, arg1, arg2);
        return(1);
    }

int
isNumber(char *string)
{
    /* return 1 if string is a number */
    int i;
    return( (sscanf(string, "%d", &i)) == 1);
}

```

10. Code Fragment for Simulator

Here is some C code that may help you write the simulator. Again, you should take this merely as a hint. You may have to re-code this to make it do exactly what you want, but this should help you get started. Remember not to change stateStruct or printState.

```

/* instruction-level simulator for LC3101 */

#include <stdio.h>
#include <string.h>

#define NUMMEMORY 65536 /* maximum number of words in memory */
#define NUMREGS 8 /* number of machine registers */
#define MAXLINELENGTH 1000

typedef struct stateStruct {
    int pc;
    int mem[NUMMEMORY];
    int reg[NUMREGS];
    int numMemory;
} stateType;

void printState(stateType *);

int
main(int argc, char *argv[])
{
    char line[MAXLINELENGTH];
    stateType state;
    FILE *filePtr;

    if (argc != 2) {

```

bits. Neither a nor b are changed. E.g. $(25 \gg 2)$ is 6. Note that 25 is 11001 in binary, and 6 is 110 in binary.

3) The value of the expression $(a \ll b)$ is the number "a" shifted left by "b" bits. Neither a nor b are changed. E.g. $(25 \ll 2)$ is 100. Note that 25 is 11001 in binary, and 100 is 1100100 in binary.

4) To find the value of the expression $(a \& b)$, perform a logical AND on each bit of a and b (i.e. bit 31 of a AND'ed with bit 31 of b, bit 30 of a AND'ed with bit 30 of b, etc.). E.g. $(25 \& 11)$ is 9, since:

```
    11001 (binary)
    & 01011 (binary)
    -----
    = 01001 (binary), which is 9 decimal.
```

5) To find the value of the expression $(a | b)$, perform a logical OR on each bit of a and b (i.e. bit 31 of a OR'ed with bit 31 of b, bit 30 of a OR'ed with bit 30 of b, etc.). E.g. $(25 | 11)$ is 27, since:

```
    11001 (binary)
    | 01011 (binary)
    -----
    = 11011 (binary), which is 27 decimal.
```

6) $\sim a$ is the bit-wise complement of a (a is not changed).

Use these operations to create and manipulate machine-code. E.g. to look at bit 3 of the variable a, you might do: $(a \gg 3) \& 0x1$. To look at bits (bits 15-12) of a 16-bit word, you could do: $(a \gg 12) \& 0xF$. To put a 6 into bits 5-3 and a 3 into bits 2-1, you could do: $(6 \ll 3) | (3 \ll 1)$. If you're not sure what an operation is doing, print some intermediate results to help you debug.
